# Automated Detection of Non-Termination and NullPointerExceptions for Java Bytecode<sup>\*</sup>

Marc Brockschmidt, Thomas Ströder, Carsten Otto, and Jürgen Giesl

LuFG Informatik 2, RWTH Aachen University, Germany

**Abstract.** Recently, we developed an approach for automated termination proofs of Java Bytecode (JBC), which is based on constructing and analyzing *termination graphs*. These graphs represent all possible program executions in a finite way. In this paper, we show that this approach can also be used to detect *non-termination* or `NullPointerExceptions`. Our approach automatically generates *witnesses*, i.e., calling the program with these witness arguments indeed leads to non-termination resp. to a `NullPointerException`. Thus, we never obtain “false positives”. We implemented our results in the termination prover AProVE and provide experimental evidence for the power of our approach.

## 1 Introduction

To use program verification in the software development process, one is not only interested in proving the validity of desired program properties, but also in providing a witness (i.e., a counterexample) if the property is violated.

Our approach is based on our earlier work to prove termination of JBC [4, 6, 17]. Here, a JBC program is first automatically transformed to a *termination graph* by symbolic evaluation. Afterwards, a term rewrite system is generated from the termination graph and existing techniques from term rewriting are used to prove termination of the rewrite system. As shown in the annual *International Termination Competition*,<sup>1</sup> our corresponding tool AProVE is currently among the most powerful ones for automated termination proofs of Java programs.

*Termination graphs* finitely represent all runs through a program for a certain set of input values. Similar graphs were used for many kinds of program analysis (e.g., to improve the efficiency of software verification [7], or to ensure termination of program optimization [22]). In this paper, we show that termination graphs can also be used to detect non-termination and `NullPointerExceptions`.

In Sect. 2, we recapitulate termination graphs. In contrast to [4, 6, 17], we also handle programs with *arrays* and we present an algorithm to *merge* abstract states in a termination graph which is needed in order to keep termination graphs finite. In Sect. 3 we show how to automatically generate *witness states* (i.e., suitable inputs to the program) which result in errors like `NullPointerExceptions`. Sect. 4 presents our approach to detect non-termination. Here, we use an SMT

solver to find different forms of non-terminating loops and the technique of Sect. 3 is applied to generate appropriate witness states.

Concerning the detection of `NullPointerException`s, most existing techniques try to prove *absence* of such exceptions (e.g., [15, 23]), whereas our approach tries to prove *existence* of `NullPointerException`s and provides counterexamples which indeed lead to such exceptions. So in contrast to bug finding techniques like [2, 9], our approach does not yield “false positives”.

Methods to detect *non-termination* automatically have for example been studied for term rewriting (e.g., [11, 19]) and logic programming (e.g., [18]). We are only aware of two existing tools for automated non-termination analysis of Java: The tool `Julia` transforms JBC programs into constraint logic programs, which are then analyzed for non-termination [20]. The tool `Invel` [24] investigates non-termination of Java programs based on a combination of theorem proving and invariant generation using the `KeY` [3] system. In contrast to `Julia` and to our approach, `Invel` only has limited support for programs operating on the heap. Moreover, neither `Julia` nor `Invel` return witnesses for non-termination. In Sect. 5 we compare the implementation of our approach in the tool `AProVE` with `Julia` and `Invel` and show that our approach indeed leads to the most powerful automated non-termination analyzer for Java so far.

Moreover, [14] presents a method for non-termination proofs of C programs. In contrast to our approach, [14] can deal with non-terminating recursion and integer overflows. On the other hand, [14] cannot detect *non-periodic* non-termination (where there is no fixed sequence of program positions that is repeated infinitely many times), whereas this is no problem for our approach, cf. Sect. 4.2.

There also exist tools for testing C programs in a randomized way, which can detect candidates for potential non-termination bugs (e.g., [13, 21]). However, they do not provide a proof for non-termination and may return “false positives”.

## 2 Termination Graphs

```
public class Loop {
    public static void main(String[] a){
        int i = 0;
        int j = a.length;
        while (i < j) {
            i += a[i].length(); }}}
```

Fig. 1. Java Program

We illustrate our approach by the `main` method of the Java program in Fig. 1. The `main` method is the entry point when starting a program. Its only argument is an array of `String` objects corresponding to the arguments specified on the command line. To avoid dealing with all syntactic constructs of Java, we analyze JBC instead. JBC [16] is an assembly-like

```
main(String[] a):
00: iconst_0      #load 0 to stack
01: istore_1     #store to i
02: aload_0      #load a to stack
03: arraylength  #get array length
04: istore_2     #store to j
05: iload_1      #load i to stack
06: iload_2      #load j to stack
07: if_icmpge 22 #jump to end if i >= j
10: iload_1      #load i to stack
11: aload_0      #load a to stack
12: iload_1      #load i to stack
13: aaload       #load a[i]
14: invokevirtual length #call length()
17: iadd         #add length and i
18: istore_1     #store to i
19: goto 05
22: return
length():
00: aload_0      #load this to stack
01: getfield count #load count field
04: ireturn     #return it
```

Fig. 2. JBC Program

object-oriented language designed as intermediate format for the execution of Java. The corresponding JBC for our example, obtained automatically by the standard `javac` compiler, is shown in Fig. 2 and will be explained in Sect. 2.2.

The method `main` increments `i` by the length of the `i`-th input string until `i` exceeds the number `j` of input arguments. It combines two typical problems:

- (a) The accesses to `a.length` and `a[i].length()` are not guarded by appropriate checks to ensure memory safety. Thus, if `a` or `a[i]` are `null`, the method ends with a `NullPointerException`. While this cannot happen when the method is used as an entry point for the program, another method could for instance contain `String[] b = {null}; Loop.main(b)`.
- (b) The method may not terminate, as the input arguments could contain the empty string. If `a[i] = ""`, then the counter `i` is not increased, leading to *looping* non-termination, as the same program state is visited again and again. For instance, the call `java Loop ""` does not terminate.

We show how to automatically detect such problems and to synthesize appropriate witnesses in Sect. 3 and 4. Our approach is based on *termination graphs* that over-approximate all program executions. After introducing our notion of states in Sect. 2.1, we describe the construction of termination graphs in Sect. 2.2. Sect. 2.3 shows how to create “merged” states representing two given states.

## 2.1 Abstract States

Our approach is related to *abstract interpretation* [8], since the states in termination graphs are *abstract*, i.e., they represent a (possibly infinite) set of concrete system configurations of the program. We define the set of all states as  $\text{STATES} = (\text{PPOS} \times \text{LOCVAR} \times \text{OPSTACK})^* \times (\{\perp\} \cup \text{REFS}) \times \text{HEAP} \times \text{ANNOTATIONS}$ .

Consider the program from Fig. 1. The initial state  $A$  in Fig. 3 represents all system configurations entering the `main` method with arbitrary tree-shaped (and thus, acyclic) non-`null` arguments. A state consists of four parts: the call stack, exception information, the heap, and annotations for possible sharing effects.

The call stack consists of stack frames, where *several* frames may occur due to method calls. For readability, we exclude recursive programs, but our results easily extend to the approach of [6] for recursion. We also disregard multi-threading, reflection, static fields, static initialization of classes, and floats.

Each stack frame has three components. We write the frames of the call stack below each other and separate their components by “|”. The first component of a frame is the program position, indicated by the number of the next instruction (00 in Fig. 3). The second component represents the local variables by a list of references to the heap, i.e.,  $\text{LOCVAR} = \text{REFS}^*$ . To avoid a special treatment of primitive values, we also represent them by references. In examples, we write the names of variables instead of their indices. Thus, “`a:a1`” means that the value of the 0-th local variable `a` is the reference `a1` (i.e., `a1` is the address of an array object). Of course, different local variables can point to the same address. The third component is the operand stack that JBC instructions work on, where  $\text{OPSTACK} = \text{REFS}^*$ . The empty stack is “ $\varepsilon$ ” and “`i6, i4`” is a stack with `i6` on top.

00   a: a <sub>1</sub>   ε a <sub>1</sub> : String[] i <sub>1</sub> i <sub>1</sub> : [≥0]
--

**Fig. 3.** State  $A$

Information about thrown exceptions is represented in the second part of our states. If no exception is currently thrown, this part is  $\perp$  (which we do not display in example states). Otherwise it is a reference to the exception object.

Below the call stack, information about the heap is given by a partial function from  $\text{HEAP} = \text{REFS} \rightarrow (\text{INTEGERS} \cup \text{UNKNOWN} \cup \text{INSTANCES} \cup \text{ARRAYS} \cup \{\text{null}\})$  and by a set of annotations which specify possible sharing effects.

Our representation of integers abstracts from the different bounded types of integers in Java and considers arbitrary integer numbers instead (i.e., we do not handle overflows). To represent unknown integer values, we use possibly unbounded intervals, i.e.,  $\text{INTEGERS} = \{\{x \in \mathbb{Z} \mid a \leq x \leq b\} \mid a \in \mathbb{Z} \cup \{-\infty\}, b \in \mathbb{Z} \cup \{\infty\}, a \leq b\}$ . We abbreviate  $(-\infty, \infty)$  by  $\mathbb{Z}$  and intervals like  $[0, \infty)$  by  $[\geq 0]$ . So “ $i_1: [\geq 0]$ ” means that any non-negative integer can be at the address  $i_1$ .

$\text{CLASSNAMES}$  contains the names of all classes and interfaces in the program.  $\text{TYPES} = \text{CLASSNAMES} \cup \{t[] \mid t \in \text{TYPES}\}$  contains  $\text{CLASSNAMES}$  and all resulting array types. So a type  $t[]$  can be generated from any type  $t$  to describe arrays with entries of type  $t$ .<sup>2</sup> We call  $t'$  a *subtype* of  $t$  iff  $t' = t$ ; or  $t'$  *extends*<sup>3</sup> or *implements* a subtype of  $t$ ; or  $t' = \hat{t}[], t = \hat{t}[],$  and  $\hat{t}$  is a subtype of  $\hat{t}$ .

The values in  $\text{UNKNOWN} = \text{TYPES} \times \{?\}$  represent tree-shaped (and thus acyclic) objects and arrays where we have no information except the type. For example, for a class `List` with the field `next` of type `List`, “ $o_1 : \text{List}(?)$ ” means that the object at address  $o_1$  is `null` or of a subtype of `List`.

$\text{INSTANCES}$  represent objects of some class. They are described by the values of their fields, i.e.,  $\text{INSTANCES} = \text{CLASSNAMES} \times (\text{FIELDIDS} \rightarrow \text{REFS})$ . For cases where field names are overloaded, the  $\text{FIELDIDS}$  also contain the respective class name to avoid ambiguities, but we usually do not display it in our examples. So “ $o_1 : \text{List}(\text{next} = o_2)$ ” means that at the address  $o_1$ , there is a `List` object and the value of its field `next` is  $o_2$ . For all  $(cl, f) \in \text{INSTANCES}$ , the function  $f$  is defined for all fields of the class  $cl$  and all of its superclasses.

In contrast to our earlier papers [4, 6, 17], in this paper we also show how to handle *arrays*. An array can be represented by an element from  $\text{TYPES} \times \text{REFS}$  denoting the array’s type and length (specified by a reference to an integer value). For instance, “ $a_1 : \text{String}[] i_1$ ” means that at the address  $a_1$ , there is a `String` array of length  $i_1$ . Alternatively, the array representation can also contain an additional list of references for the array entries. So “ $a_2 : \text{String}[] i_1 \{o_1, o_2\}$ ” denotes that at the address  $a_2$ , we have a `String` array of length  $i_1$ , and its entries are  $o_1$  and  $o_2$ . Thus,  $\text{ARRAYS} = (\text{TYPES} \times \text{REFS}) \cup (\text{TYPES} \times \text{REFS} \times \text{REFS}^*)$ .

In our representation, no sharing can occur unless explicitly stated. So an abstract state containing the references  $o_1, o_2$  and not mentioning that they could be sharing, only represents concrete states where  $o_1$  and the references reachable from  $o_1$  are disjoint<sup>4</sup> from  $o_2$  and the references reachable from  $o_2$ . Moreover, then the objects at  $o_1$  and  $o_2$  must be tree-shaped (and thus acyclic).

<sup>2</sup> We do not consider arrays of primitives in this paper, but our approach can easily be extended to handle them, as we did in our implementation.

<sup>3</sup> For example, any type (implicitly) *extends* the type `java.lang.Object`.

<sup>4</sup> Disjointness is not required for references pointing to `INTEGERS` or to `null`.

Certain sharing effects are represented directly (e.g., “ $o_1:\text{List}(\text{next}=o_1)$ ” is a cyclic singleton list). Other sharing effects are represented by three kinds of *annotations*, which are only built for references  $o$  where  $h(o) \notin \text{INTEGERS} \cup \{\text{null}\}$  for the heap  $h$ . The first kind of annotation is called *equality annotation* and has the form “ $o_1 =? o_2$ ”. Its meaning is that the addresses  $o_1$  and  $o_2$  could be equal. We only use such annotations if the value of at least one of  $o_1$  and  $o_2$  is UNKNOWN. *Joinability annotations* are the second kind of annotation. They express that two objects “may join” ( $o_1 \searrow o_2$ ). We say that a non-integer and non-null reference  $o'$  is a direct successor of  $o$  in a state  $s$  (denoted  $o \rightarrow_s o'$ ) iff the object at address  $o$  has a field whose value is  $o'$  or if the array at address  $o$  has  $o'$  as one of its entries. The meaning of “ $o_1 \searrow o_2$ ” is that there could be an  $o$  with  $o_1 \rightarrow_s^* o \leftarrow_s^+ o_2$  or  $o_1 \rightarrow_s^+ o \leftarrow_s^* o_2$ , i.e.,  $o$  is a common successor of the two references. However,  $o_1 \searrow o_2$  does not imply  $o_1 =? o_2$ . Finally, as the third type of annotations, we use *cyclicity annotations* “ $o!$ ” to denote that the object at address  $o$  is not necessarily tree-shaped (so in particular, it could be cyclic).

## 2.2 Constructing Termination Graphs

Starting from the initial state  $A$ , the termination graph in Fig. 4 is constructed by symbolic evaluation. In the first step, we have to evaluate `iconst_0`, i.e., we load the integer 0 on top of the operand stack. The second instruction `istore_1` stores the value 0 on top of the operand stack in the first local variable `i`.<sup>5</sup>

After that, the value of the 0-th local variable `a` (the array in the input argument) is loaded on the operand stack and the instruction `arraylength` retrieves its (unknown) length  $i_1$ . That value is then stored in the second local variable `j` using the instruction `istore_2`. This results in the state  $B$  in Fig. 4. We connect  $A$  and  $B$  by a dotted arrow, indicating several evaluation steps (i.e., we omitted the states between  $A$  and  $B$  for space reasons in Fig. 4).

From  $B$  on, we load the values of `i` and `j` on the operand stack and reach  $C$ .<sup>6</sup> The instruction `if_icmpge` branches depending on the relation of the two elements on top of the stack. However, based on the knowledge in  $C$ , we cannot determine whether `i >= j` holds. Thus, we perform a case analysis (called *integer refinement* [4, Def. 1]), obtaining two new states  $D$  and  $E$ . We label the *refinement edges* from  $C$  to  $D$  and  $E$  (represented by dashed arrows) by the reference  $i_1$  that was refined. In  $D$ , we assume that `i >= j` holds. Hence,  $i_1$  (corresponding to `j`) is  $\leq 0$  and from  $i_1 : [\geq 0]$  in state  $C$  we conclude that  $i_1$  is 0. We thus reach instruction 22 (`return`), where the program ends (denoted by  $\square$ ).

In  $E$ , we consider the other case and replace  $i_1$  by  $i_2$ , which only represents positive integers. We mark what relation holds in this case by labeling the evaluation edge from  $E$  to its successor with  $0 < i_2$ . In general, we always use a fresh reference name like  $i_2$  when generating new values by a case analysis, to

<sup>5</sup> If we have a reference whose value is from a singleton interval like  $[0, 0]$  or `null`, we replace all its occurrences in states by 0 resp. by `null`. So in state  $B$ , we simply write “`i:0`”. Such abbreviations will also be used in the labels of edges.

<sup>6</sup> The box around  $C$  and the following states is dashed to indicate that these states will be removed from the termination graph later on.

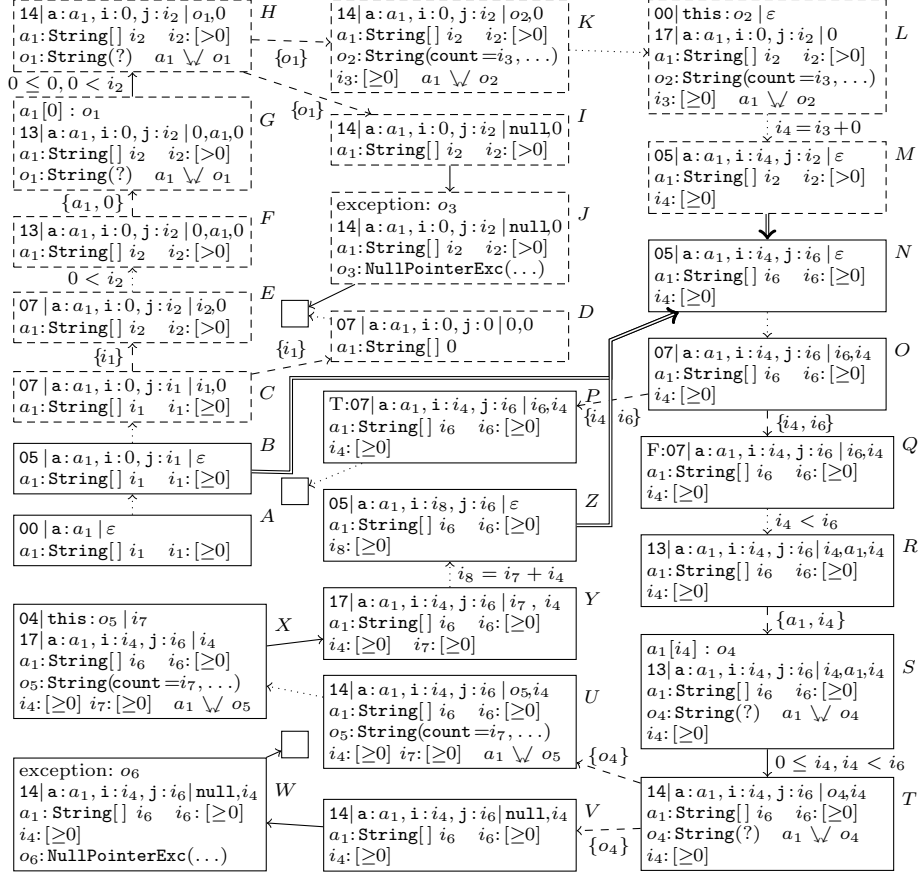

Fig. 4. Termination Graph

ensure single static assignments, which will be useful in the analysis later on. We continue with instruction 10 and load the values of  $i$ ,  $a$ , and  $i$  on the operand stack, obtaining state  $F$ . To evaluate `aaload` (i.e., to load the 0-th element from the array  $a_1$  on the operand stack), we add more information about  $a_1$  at the index 0 and label the refinement edge from  $F$  to  $G$  accordingly. In  $G$ , we created some object  $o_1$  for the 0-th entry of the array  $a_1$  and marked that  $o_1$  is reachable from  $a_1$  by adding the *joinability annotation*  $a_1 \ \surd \ o_1$ .<sup>7</sup>

Now evaluation of `aaload` moves  $o_1$  to the operand stack in state  $H$ . Whenever an array access succeeds, we label the corresponding edge by the condition that the used index is  $\geq 0$  and smaller than the length of the array.

In  $H$ , we need to `invoke` the method `length()` on the object  $o_1$ . However, we do not know whether  $o_1$  is `null` (which would lead to a `NullPointerException`).

<sup>7</sup> If we had already retrieved another value  $o'$  from the array  $a_1$ , it would also have been annotated with  $a_1 \ \surd \ o'$  and we would consequently add  $o_1 \ \surd \ o'$  and  $o_1 =^? o'$  when retrieving  $o_1$ , indicating that the two values may share or even be equal.

Hence, we perform an *instance refinement* [4, Def. 5] and label the edges from  $H$  to the new states  $I$  and  $K$  by the reference  $o_1$  that is refined. In  $I$ ,  $o_1$  has the value `null`. In  $K$ , we replace the reference  $o_1$  by  $o_2$ , pointing to a concrete `String` object with unknown field values. In Fig. 4, we only display the field `count`, containing the integer reference  $i_3$ . In this instance refinement, one uses the special semantics of the pre-defined `String` class to conclude that  $i_3$  can only point to a non-negative integer, as `count` corresponds to the *length* of the string. In  $I$ , further evaluation results in a `NullPointerException`. A corresponding exception object  $o_3$  is generated and the exception is represented in  $J$ . As no exception handler is defined, evaluation ends and the program terminates.

In  $K$ , calling `length()` succeeds. In  $L$ , a new stack frame is put on top of the call stack, where the implicit argument `this` is set to  $o_2$ . In the called method `length()`, we load  $o_2$  on the operand stack and get the value  $i_3$  of its field `count`. We then return from `length()`, add the returned value  $i_3$  to 0, and store the result in the variable `i`. Afterwards, we jump back to instruction 05. This is shown in state  $M$  and the computation  $i_4 = i_3 + 0$  is noted on the evaluation edge.

But now  $M$  is at the same program position as  $B$ . Continuing our symbolic evaluation would lead to an infinite tree, as we would always have to consider the case where the loop condition `i < j` is still true. Instead, our goal is to obtain a finite termination graph. The solution is to automatically generate a new state  $N$  which represents all concrete states that are represented by  $B$  or  $M$  (i.e.,  $N$  results from *merging*  $B$  and  $M$ ). Then we can insert *instance edges* from  $B$  and  $M$  to  $N$  (displayed by double arrows) and continue the graph construction with  $N$ .

### 2.3 Instantiating and Merging States

To find differences between states and to merge states, we introduce *state positions*. Such a position describes a “path” through a state, starting with some local variable, operand stack entry, or the exception object and then continuing through fields of objects or entries of arrays. For the latter, we use the set  $\text{ARRAYIDXs} = \{[j] \mid j \geq 0\}$  to describe the set of all possible array indices.

**Definition 1 (State Positions SPos).** *Let  $s = (\langle fr_0, \dots, fr_n \rangle, e, h, a)$  be a state where each stack frame  $fr_i$  has the form  $(pp_i, lv_i, os_i)$ . Then  $\text{SPOS}(s)$  is the smallest set containing all the following sequences  $\pi$ :*

- $\pi = LV_{i,j}$  where  $0 \leq i \leq n$ ,  $lv_i = \langle o_{i,0}, \dots, o_{i,m_i} \rangle$ ,  $0 \leq j \leq m_i$ . Then  $s|_\pi$  is  $o_{i,j}$ .
- $\pi = OS_{i,j}$  where  $0 \leq i \leq n$ ,  $os_i = \langle o'_{i,0}, \dots, o'_{i,k_i} \rangle$ ,  $0 \leq j \leq k_i$ . Then  $s|_\pi$  is  $o'_{i,j}$ .
- $\pi = \text{EXC}$  if  $e \neq \perp$ . Then  $s|_\pi$  is  $e$ .
- $\pi = \pi' v$  for some  $v \in \text{FIELDIDS}$  and some  $\pi' \in \text{SPOS}(s)$  where  $h(s|_{\pi'}) = (cl, f) \in \text{INSTANCES}$  and where  $f(v)$  is defined. Then  $s|_\pi$  is  $f(v)$ .
- $\pi = \pi' \text{LEN}$  for some  $\pi' \in \text{SPOS}(s)$  where  $h(s|_{\pi'}) = (t, i) \in \text{ARRAYS}$  or  $h(s|_{\pi'}) = (t, i, d) \in \text{ARRAYS}$ . Then  $s|_\pi$  is  $i$ .
- $\pi = \pi' [j]$  for some  $[j] \in \text{ARRAYIDXs}$  and some  $\pi' \in \text{SPOS}(s)$ , where  $h(s|_{\pi'}) = (t, i, \langle r_0, \dots, r_q \rangle) \in \text{ARRAYS}$  and  $0 \leq j \leq q$ . Then  $s|_\pi$  is  $r_j$ .

For any position  $\pi$ , let  $\bar{\pi}_s$  denote the maximal prefix of  $\pi$  such that  $\bar{\pi}_s \in \text{SPOS}(s)$ . We write  $\bar{\pi}$  if  $s$  is clear from the context.

For example, in state  $K$ , the position  $\pi = \text{OS}_{0,0}$  `count` refers to the reference  $i_3$ , i.e., we have  $K|_\pi = i_3$  and for the position  $\tau = \text{LV}_{0,0}$  `LEN`, we have  $K|_\tau = i_2$ . As the field `count` was introduced between  $H$  and  $K$  by an instance refinement, we have  $\pi \notin \text{SPOS}(H)$  and  $\bar{\pi}_H = \text{OS}_{0,0}$ , where  $H|_{\bar{\pi}} = o_1$ . We can now see that  $B$  and  $M$  only differ in the positions  $\text{LV}_{0,0}$  `LEN`,  $\text{LV}_{0,1}$ , and  $\text{LV}_{0,2}$ .

A state  $s'$  is an *instance* of another state  $s$  (denoted  $s' \sqsubseteq s$ ) if both are at the same program position and if whenever there is a reference  $s'|_\pi$ , then either the values represented by  $s'|_\pi$  in the heap of  $s'$  are a subset of the values represented by  $s|_\pi$  in the heap of  $s$  or else,  $\pi \notin \text{SPOS}(s)$ . Moreover, shared parts of the heap in  $s'$  must also be shared in  $s$ . As we only consider verified JBC programs, the fact that  $s$  and  $s'$  are at the same program position implies that they have the same number of local variables and their operand stacks have the same size. For a formal definition of “instance”, we refer to Def. 9 in the appendix, where we extended the “instance” definition from [4, Def. 3] to arrays.

For example,  $B$  is not an instance of  $M$  since  $h_B(B|_{\text{LV}_{0,2}}) = [0, \infty) \not\subseteq [1, \infty) = h_M(M|_{\text{LV}_{0,2}})$  for the heaps  $h_B$  and  $h_M$  of  $B$  and  $M$ . Similarly,  $M \not\subseteq B$  because  $h_M(M|_{\text{LV}_{0,1}}) = [0, \infty) \not\subseteq \{0\} = h_B(B|_{\text{LV}_{0,1}})$ . However, we can automatically synthesize a “merged” (or “widened”) state  $N$  with  $B \sqsubseteq N$  and  $M \sqsubseteq N$  by choosing the values for common positions  $\pi$  in  $B$  and  $M$  to be the union of the values in  $B$  and  $M$ , i.e.,  $h_N(N|_\pi) = h_B(B|_\pi) \cup h_M(M|_\pi)$ . Thus, we have  $h_N(N|_{\text{LV}_{0,2}}) = [0, \infty) \cup [1, \infty) = [0, \infty)$  and  $h_N(N|_{\text{LV}_{0,1}}) = \{0\} \cup [0, \infty) = [0, \infty)$ .

**Algorithm** `mergeStates`( $s, s'$ ):  
 $\hat{s} = \text{new State}(s)$   
**for**  $\pi \in \text{SPOS}(s) \cap \text{SPOS}(s')$ :  
     $\text{ref} = \text{mergeRef}(s|_\pi, s'|_\pi)$   
     $\hat{h}(\text{ref}) = \text{mergeVal}(h(s|_\pi), h'(s'|_\pi))$

**Fig. 5.** Merging Algorithm

This merging algorithm is illustrated in Fig. 5. Here,  $h, h', \hat{h}$  refer to the heaps of the states  $s, s', \hat{s}$ , respectively. With `new State`( $s$ ), we create a fresh state at the same program position as  $s$ . The auxiliary function `mergeRef` is an injective mapping from a pair of references to a fresh reference name. The function `mergeVal` maps two heap values to the most precise value from our abstract domains that represents both input values. For example, `mergeVal`( $[0, 1], [10, 15]$ ) is  $[0, 15]$ , covering both input values, but also adding  $[2, 9]$  to the set of represented values. For values of the same type, e.g., `String(count= $i_1, \dots$ )` and `String(count= $i_2, \dots$ )`, `mergeVal` returns a new object of same type with field values obtained by `mergeRef`, e.g., `String(count= $i_3, \dots$ )` where  $i_3 = \text{mergeRef}(i_1, i_2)$ . When merging values of differing types or `null`, a

value from UNKNOWN with the most precise common supertype is returned.

To handle sharing effects, in a second step, we check if there are “sharing” references at some positions  $\pi$  and  $\pi'$  in  $s$  or  $s'$  that do not share anymore in the merged state  $\hat{s}$ . Then we add the corresponding annotations to the maximal prefixes  $\hat{s}|_{\pi}$  and  $\hat{s}|_{\pi'}$ . Furthermore, we check if there are non-tree shaped objects at some position  $\pi$  in  $s$  or  $s'$ , i.e., if one can reach the same successor using different paths starting in position  $\pi$ . Then we add the annotation  $\hat{s}|_{\pi}!$ .

**Theorem 2.** *Let  $s, s' \in \text{STATES}$  and  $\hat{s} = \text{mergeStates}(s, s')$ . Then  $s \sqsubseteq \hat{s} \sqsupseteq s'$ .<sup>8</sup>*

In our example, we used the algorithm `mergeStates` to create the state  $N$  and draw instance edges from  $B$  and  $M$  to  $N$ . Since the computation in  $N$  also represents the states  $C$  to  $M$  (marked by dashed borders), we now remove them.

We continue symbolic evaluation in  $N$ , reaching state  $O$ , which is like  $C$ . In  $C$ , we refined our information to decide whether the condition  $i \geq j$  of `if_icmpge` holds. However, now this case analysis cannot be expressed by simply refining the intervals from INTEGERS that correspond to the references  $i_6$  and  $i_4$  (i.e., a relation like  $i_4 \geq i_6$  is not expressible in our states). Instead, we again generate successors for both possible values of the condition  $i \geq j$ , but do not change the actual information about our values. In the resulting states  $P$  and  $Q$ , we mark the truth value of the condition  $i \geq j$  by “T” and “F”. The refinement edges from  $O$  to  $P$  and  $Q$  are marked by the references  $i_4$  and  $i_6$  that are refined.  $P$  leads to a program end, while we continue the symbolic evaluation in  $Q$ . As before, we label the refinement edge from  $Q$  to  $R$  by  $i_4 < i_6$ .

$R$  and  $S$  are like  $F$  and  $G$ . The refinement edge from  $R$  to  $S$  is labeled by  $a_1$  and  $i_4$  which were refined in order to evaluate `aaload` (note that since we only reach  $R$  if  $i_4 < i_6$ , the array access succeeds). As in  $H$ , we then perform an instance refinement to decide whether calling `length()` on the object  $o_4$  succeeds, leading to  $U$  and  $V$ . From  $V$ , we again reach a program end after a `NullPointerException` was thrown in  $W$ . From  $U$ , we reach  $X$  by evaluating the call to `length()`. Between  $X$  to  $Y$ , we return from `length()`. After that, we add the two non-negative integers  $i_7$  and  $i_4$ , creating a non-negative integer  $i_8$ . The edge from  $Y$  to  $Z$  is labeled by the computation  $i_8 = i_7 + i_4$ .

$Z$  is again an instance of  $N$ . We can also use the algorithm `mergeStates` to determine whether one state is an instance of another: When merging  $s, s'$  to obtain a new state  $\hat{s}$ , one adapts `mergeStates` such that the algorithm terminates with failure whenever we widen a value of  $s$  or add an annotation to  $\hat{s}$  that did not exist in  $s$  (e.g., when we add  $\hat{s}|_{\pi} = ? \hat{s}|_{\pi'}$  and there is no  $s|_{\pi} = ? s|_{\pi'}$ ). Then the algorithm terminates successfully iff  $s' \sqsubseteq s$  holds. After drawing the instance edge from  $Z$  to  $N$  (yielding a *cycle* in our graph), all leaves of the graph are program ends and thus the graph construction is finished.

We now define termination graphs formally. We extend our earlier definition from [4] slightly by labeling edges with information about the performed refinements and about the relations of integers. Let  $\text{RelOp} = \{i \circ i' \mid i, i' \in \text{REFS}, \circ \in \{<, \leq, =, \neq, \geq, >\}\}$  denote the set of relations between two integer references such as  $i_4 < i_6$  and  $\text{ArithOp} = \{i = i' \bowtie i'' \mid i, i', i'' \in \text{REFS}, \bowtie \in \{+, -, *, /, \% \}\}$

<sup>8</sup> For all proofs, we refer to the appendix.

denote the set of arithmetic computations such as  $i_8 = i_7 + i_4$ .

Termination graphs are constructed by repeatedly expanding those leaves that do not correspond to program ends. Whenever possible, we use *symbolic evaluation*  $\xrightarrow{SyEv}$ . Here,  $\xrightarrow{SyEv}$  extends the usual evaluation relation for JBC such that it can also be applied to *abstract* states representing several concrete states. For a formal definition of  $\xrightarrow{SyEv}$ , we refer to [4, Def. 6]. In the termination graph, the corresponding *evaluation edges* can be labeled by a set  $C \subseteq \text{ArithOp} \cup \text{RelOp}$  which corresponds to the arithmetic operations and (implicitly) checked relations in the evaluation. For example, when accessing the index  $i$  of an array  $a$  succeeds, we have implicitly ensured  $0 \leq i$  and  $i < a.\text{length}$  and this is noted in  $C$ .

If symbolic evaluation is not possible, we refine the information for some references  $R$  by case analysis and label the resulting *refinement edges* with  $R$ .

To obtain a *finite* graph, we create a more general state by *merging* whenever a program position is visited a second time in our symbolic evaluation and add appropriate *instance edges* to the graph. However, we require all cycles of the termination graph to contain at least one evaluation edge. By using an appropriate strategy for merging resp. widening states, we can automatically generate a finite termination graph for any program.

**Definition 3 (Termination Graph).** *A graph  $(V, E)$  with  $V \subseteq \text{STATES}$ ,  $E \subseteq V \times ((\{\text{EVAL}\} \times 2^{\text{ArithOp} \cup \text{RelOp}}) \cup (\{\text{REFINE}\} \times 2^{\text{REFS}}) \cup \{\text{INS}\}) \times V$  is a termination graph if every cycle contains at least one edge labeled with some  $\text{EVAL}_C$  and one of the following holds for each  $s \in V$ :*

- *$s$  has just one outgoing edge  $(s, \text{EVAL}_C, s')$ ,  $s \xrightarrow{SyEv} s'$ , and  $C$  is the set of integer relations that are checked (resp. generated) in this step*
- *the outgoing edges of  $s$  are  $(s, \text{REFINE}_R, s_1), \dots, (s, \text{REFINE}_R, s_n)$  and  $\{s_1, \dots, s_n\}$  is a refinement of  $s$  on the references  $R \subseteq \text{REFS}$*
- *$s$  has just one outgoing edge  $(s, \text{INS}, s')$  and  $s \sqsubseteq s'$*
- *$s$  has no outgoing edge and  $s = (\varepsilon, e, h, a)$  (i.e.,  $s$  is a program end)*

We refer to [6, 17] for methods to use termination graphs for termination proofs and to [4] for soundness proofs which show that if  $c$  is a concrete state with  $c \sqsubseteq s$  for some state  $s$  in the termination graph, then the JBC evaluation of  $c$  is represented in the termination graph. In Sect. 3 and 4 we show how to use termination graphs to detect `NullPointerException`s and non-termination.

### 3 Generating Witnesses for `NullPointerException`s

In our example, an uncaught `NullPointerException` is thrown in the “error state”  $W$ , leading to a program end. Such violations of memory safety can be immediately detected from the termination graph. In particular, if the graph does not contain any such exceptions, then memory safety is proved.<sup>9</sup>

To report a possible violation of memory safety to the user, we now show

<sup>9</sup> In languages like C, *memory safety* (or *pointer safety*) means absence of (i) accesses to `null`, (ii) dangling pointers, and (iii) memory leaks [25]. In Java, (ii) and (iii) are ensured by the JVM and only `NullPointerException`s can destroy memory safety.

how to automatically generate a *witness* (i.e., an assignment to the arguments of the program) that leads to the exception. Our termination graph allows us to generate such witnesses automatically. This technique for witness generation will also be used to construct witnesses for non-termination in Sect. 4.

So our goal is to find a *witness state*  $A'$  for the initial state  $A$  of the method `main` w.r.t. the “error state”  $W$ . This state  $A'$  describes a subset of arguments, all of which lead to an instance of  $W$ , i.e., to a `NullPointerException`.

**Definition 4 (Witness State).** *Let  $s, s', w \in \text{STATES}$ . The state  $s'$  is a witness state for  $s$  w.r.t.  $w$  iff  $s' \sqsubseteq s$  and  $s' \xrightarrow{SyEv^*} w'$  for some state  $w' \sqsubseteq w$ .*

To obtain a witness state  $A'$  for  $A$  automatically, we start with the error state  $W$  and traverse the edges of the termination graph backwards until we reach  $A$ . In general, let  $s_0, s_1, \dots, s_n = w$  be a path in the termination graph from the initial state  $s_0$  to the error state  $s_n$ . Assuming that we already have a witness state  $s'_i$  for  $s_i$  w.r.t.  $w$ , we show how to generate a witness state  $s'_{i-1}$  for  $s_{i-1}$  w.r.t.  $w$ . To this end, we revert the changes done to the state  $s_{i-1}$  when creating the state  $s_i$  during the construction of the termination graph (i.e., we apply the rules for termination graph construction “backwards”). Of course, this generation of witness states can fail (in particular, this happens for error states that are not reachable from any concrete instantiation of the initial state  $s_0$ ). So in this way, our technique for witness generation is also used as a check whether certain errors can really result from initial method calls.

In our example, the error state is  $W$ . Trivially,  $W$  itself is a witness state for  $W$  w.r.t.  $W$ . The only edge leading to  $W$  is from  $V$ . Thus, we now generate a witness state  $V'$  for  $V$  w.r.t.  $W$ . The edge from  $V$  to  $W$  represents the evaluation of the instruction `invokevirtual` that triggered the exception. Reversing this instruction is straightforward, as we only have to remove the exception object from  $W$  again. Thus,  $V$  is a witness state for  $V$  w.r.t.  $W$ .

The only edge leading to  $V$  is a refinement edge from  $T$ . As a refinement corresponds to a case analysis, the information in the target state is more precise. Hence, we can reuse the witness state for  $V$ , since  $V$  is an instance of  $T$ . So  $V$  is also a witness state for  $T$  w.r.t.  $W$ .

To reverse the edge between  $T$  and  $S$ , we have to undo the instruction `aaload`. This is easy since  $S$  contains the information that the entry at index  $i_4$  in the array  $a_1$  is  $o_4$ . Thus the witness state  $S'$  for  $S$  w.r.t.  $W$  is like  $S$ , but here  $o_4$ 's value is not an unknown object, but `null`. Reversing the refinement between  $S$  and  $R$  is more complex. Note that not every state represented by  $R$  leads to a `NullPointerException`. In  $S$  we had noted the relation between the newly created reference  $o_4$  and the original array  $a_1$ . In other words, in  $S$  we know that  $a_1[i_4]$  is  $o_4$ , where  $o_4$  has the value `null` in the witness state  $S'$  for  $S$ . But in  $R$ ,  $o_4$  is missing. To solve this problem, in the witness state  $R'$  for  $R$ , we instantiate the abstract array  $a_1$  by a concrete one that contains the entry `null` at the index  $i_4$ . We use a simple heuristic<sup>10</sup> to choose a suitable

13  a: a <sub>2</sub> , i: 0, j: 1  0, a <sub>2</sub> , 0 a <sub>2</sub> : String[] 1 {null}
---

**Fig. 6.** State  $R'$

<sup>10</sup> Such heuristics cannot affect soundness, but just the power of our approach (choosing unsuitable values may prevent us from finding a witness for the initial state).

length  $i_6$  for this concrete array, which tries to find “minimal” values. Here, our heuristic chooses  $a_1$  to be an array of length one (i.e.,  $i_6$  is chosen to be 1), which only contains the entry `null` (at the index 0, i.e.,  $i_4$  is chosen to be 0). The resulting witness state  $R'$  for  $R$  w.r.t.  $W$  is displayed in Fig. 6.

Reversing the evaluation steps between  $R$  and  $Q$  yields a witness state  $Q'$  for  $Q$  w.r.t.  $W$ . From  $O$  to  $Q$ , we have a refinement edge and thus,  $Q'$  is also a witness for  $O$ .

$$\begin{array}{l} 0|a:a_2|\varepsilon \\ a_2:\text{String}[] 1\{\text{null}\} \end{array}$$

**Fig. 7.** State  $A'$

The steps from  $N$  to  $O$  can also be reversed easily. In  $N$ , we use a heuristic to decide whether to follow the incoming edge from  $Z$  or from  $B$ . Our heuristic chooses  $B$  as it is more concrete than  $Z$ . From there, we continue our reversed evaluation until we reach a witness state  $A'$  for the initial state  $A$  of the method w.r.t.  $W$ , cf. Fig. 7. So any instance of  $A'$  evaluates to an instance of  $W$ , i.e., it leads to a `NullPointerException`. If the `main` method is called directly (as the entry point of the program), then the JVM ensures that the input array does not contain `null` references. But if the `main` method is called from another method, then this violation of memory safety can indeed occur, cf. problem (a) in Sect. 2.

The following theorem summarizes our procedure to generate witness states. If there is an edge from a state  $s_1$  to a state  $s_2$  in the termination graph and we already have a witness state  $s'_2$  for  $s_2$  w.r.t.  $w$ , then Thm. 5 shows how to obtain a witness state  $s'_1$  for  $s_1$  w.r.t.  $w$ . Hence, by repeated application of this construction, we finally obtain a witness state for the initial state of the method w.r.t.  $w$ . If there is an *evaluation edge* from  $s_1$  to  $s_2$ , then we first apply the reversed rules for symbolic evaluation on  $s'_2$ . Afterwards, we instantiate the freshly appearing references (for example, those overwritten by the forward symbolic evaluation) such that  $s'_1$  is indeed an instance of  $s_1$ . If there is a *refinement edge* from  $s_1$  to  $s_2$ , then the witness state  $s'_1$  is like  $s'_2$ , but when reading from abstract arrays (such as between  $R$  and  $S$ ), we instantiate the array to a concrete one in  $s'_1$ . If there is an *instance edge* from  $s_1$  to  $s_2$ , then we *intersect* the states  $s_1$  and  $s'_2$  to obtain a representation of those states that are instances of both  $s_1$  and  $s'_2$ .

**Theorem 5 (Generating Witnesses).** *Let  $(s_1, l, s_2)$  be an edge in the termination graph and let  $s'_2$  be a witness state for  $s_2$  w.r.t.  $w$ . Let  $s'_1 \in \text{STATES}$  with:*

- *if  $l = \text{EVAL}_C$ , then  $s'_1$  is obtained from  $s'_2$  by applying the symbolic evaluation used between  $s_1$  and  $s_2$  backwards. In  $s'_1$ , we instantiate freshly appearing variables such that  $s'_1 \sqsubseteq s_1$  and  $s'_1 \xrightarrow{\text{SyEv}} s'_2$  holds.*
- *if  $l = \text{REFINE}_R$ , then  $s'_1 \sqsubseteq s'_2$ .*
- *if  $l = \text{INS}$ , then  $s'_1 = s_1 \cap s'_2$  (for the definition of  $\cap$ , see [6, Def. 2]).*

*Then  $s'_1$  is a witness state for  $s_1$  w.r.t.  $w$ .*

## 4 Proving Non-Termination

Now we show how to prove non-termination automatically. Sect. 4.1 introduces a method to detect *looping* non-termination, i.e., infinite evaluations where the *interesting references* (that determine the termination behavior) are unchanged. Sect. 4.2 presents a method which can also detect *non-looping* non-termination.

## 4.1 Looping Non-Termination

For each state, we define its *interesting* references that determine the control flow and hence, the termination behavior. Which references are interesting can be deduced from the termination graph, because whenever the (changing) value of a variable may influence the control flow, we perform a refinement. Hence, the references in the labels of refinement edges are “interesting” in the corresponding states. For example, the references  $i_4$  and  $i_6$  are interesting in the state  $O$ .

We propagate the information on interesting references backwards. For evaluation edges, those references that are interesting in the target state are also interesting in the source state. Thus,  $i_4$  and  $i_6$  are also interesting in  $N$ .

When drawing refinement or instance edges, references may be renamed. But if a reference at position  $\pi$  is interesting in the target state of such an edge, the reference at  $\pi$  is also interesting in the source state. So  $i_8 = Z|_{LV_{0,1}}$  and  $i_6 = Z|_{LV_{0,2}}$  are interesting in  $Z$ , as  $i_4 = N|_{LV_{0,1}}$  and  $i_6 = N|_{LV_{0,2}}$  are interesting in  $N$ .

Furthermore, if an interesting reference  $i$  of the target state was the result of some computation (i.e., the evaluation edge is labeled with  $i = i' \bowtie i''$ ), we mark  $i'$  and  $i''$  as interesting in the source state. The edge from  $Y$  to  $Z$  has the label  $i_8 = i_7 + i_4$ . As  $i_8$  is interesting in  $Z$ ,  $i_7$  and  $i_4$  are interesting in  $Y$ .

**Definition 6 (Interesting References).** *Let  $G = (V, E)$  be a termination graph, and let  $s, s' \in V$  be some states. Then  $I(s) \subseteq \{s|_\pi \mid \pi \in \text{SPOS}(s)\}$  is the set of interesting references of  $s$ , defined as the minimal set of references with*

- if  $(s, \text{REFINE}_R, s') \in E$ , then  $R \subseteq I(s)$ .
- if  $(s, l, s') \in E$  with  $l \in \{\text{REFINE}_R, \text{INS}\}$ , then we have  $\{s|_\pi \mid \pi \in \text{SPOS}(s) \cap \text{SPOS}(s'), s'|_\pi \in I(s')\} \subseteq I(s)$ .
- if  $(s, \text{EVAL}_C, s') \in E$ , then  $I(s') \cap \{s|_\pi \mid \pi \in \text{SPOS}(s)\} \subseteq I(s)$ .
- if  $(s, \text{EVAL}_C, s') \in E$ ,  $i = i' \bowtie i'' \in C$  and  $i \in I(s')$ , then  $\{i', i''\} \subseteq I(s)$ .

Note that if there is an evaluation where the same program position is visited repeatedly, but the values of the interesting references do not change, then this evaluation will continue infinitely. We refer to this as *looping non-termination*.

To detect such non-terminating loops, we look at cycles  $s = s_0, s_1, \dots, s_{n-1}, s_n = s$  in the termination graph. Our goal is to find a state  $v \sqsubseteq s$  such that when executing the loop, the values of the interesting references in  $v$  do not change. More precisely, when executing the loop in  $v$ , one should reach a state  $v'$  with  $v' \sqsubseteq_{II} v$ . Here,  $II$  are the positions of interesting references in  $s$  and  $\sqsubseteq_{II}$  is the “instance” relation restricted to positions with prefixes from  $II$ , whereas the values at other positions are ignored. The following theorem proves that if one finds such a state  $v$ , then indeed the loop will be executed infinitely many times when starting the evaluation in a concrete instance of  $v$ .

**Theorem 7 (Looping Non-Termination).** *Let  $s$  occur in a cycle of the termination graph. Let  $II = \{\pi \in \text{SPOS}(s) \mid s|_\pi \in I(s)\}$  be the positions of interesting references in  $s$ . If there is a  $v \sqsubseteq s$  where  $v \xrightarrow{\text{SyE}v^+} v'$  for some  $v' \sqsubseteq_{II} v$ , then any concrete state that is an instance of  $v$  starts an infinite JBC evaluation.*

We now automate Thm. 7 by a technique consisting of four steps (the first

three steps find suitable states  $v$  automatically and the fourth step checks whether  $v$  can be reached from the initial state of the method). Let  $s = s_0, s_1, \dots, s_{n-1}, s_n = s$  be a cycle in the termination graph such that there is an instance edge from  $s_{n-1}$  to  $s_n$ . In Fig. 4,  $N, \dots, Z, N$  is such a cycle (i.e., here  $s$  is  $N$ ).

1. *Find suitable values for interesting integer references.* In the first step, we find out how to instantiate the interesting references of *integer* type in  $v$ . To this end, we convert the cycle  $s = s_0, \dots, s_n = s$  edge by edge to a formula  $\varphi$  over the integers. Then every model of  $\varphi$  indicates values for the interesting integer references that are not modified when executing the loop.

Essentially,  $\varphi$  is a conjunction of all constraints that the edges are labeled with. More precisely, to compute  $\varphi$ , we process each edge  $(s_i, l, s_{i+1})$ . If  $l$  is  $\text{REFINE}_R$ , then we connect the variable names in  $s_i$  and  $s_{i+1}$  by adding the equations  $s_i|_\pi = s_{i+1}|_\pi$  to  $\varphi$  for all those positions  $\pi$  where  $s_i|_\pi$  is in  $R$  and points to an integer. Thus, for the edge from  $O$  to  $Q$ , we add the trivial equations  $i_4 = i_4 \wedge i_6 = i_6$ , as the references were not renamed in this refinement step.

If  $l = \text{EVAL}_C$ , we add the constraints and computations from  $C$  to the formula  $\varphi$ .<sup>11</sup> Thus, for the edge from  $Q$  to  $R$  we add the constraint  $i_4 < i_6$ , for the edge from  $S$  to  $T$  we add  $0 \leq i_4 \wedge i_4 < i_6$ , and the edge from  $Y$  to  $Z$  yields  $i_8 = i_7 + i_4$ . If  $l$  is  $\text{INS}$ , we again connect the reference names in  $s_i$  and  $s_{i+1}$  by adding the equations  $s_i|_\pi = s_{i+1}|_\pi$  for all  $\pi \in \text{SPOS}(s_{i+1})$  that point to integers. Thus, for the edge from  $Z$  to  $N$ , we get  $i_6 = i_6 \wedge i_8 = i_4$ . So for the cycle  $N, \dots, Z, N$ ,  $\varphi$  is  $i_4 < i_6 \wedge 0 \leq i_4 \wedge i_8 = i_7 + i_4 \wedge i_8 = i_4$  (where tautologies have been removed).

To find values for the integer references that are not modified in the loop, we now try to synthesize a model of  $\varphi$ . In our example, a standard SMT solver easily proves satisfiability and returns a model like  $i_4 = 0, i_6 = 1, i_7 = 0, i_8 = 0$ .

2. *Guess suitable values for interesting non-integer references.* We want to find a state  $v \sqsubseteq s$  such that executing the loop does not change the values of interesting references in  $v$ . We have determined the values of the interesting *integer* references in  $v$  (i.e.,  $i_4$  is 0 and  $i_6$  is 1 in our example). It remains to determine suitable values for the other interesting references (i.e., for  $a_1$  in our example)

To this end, we use the following heuristic. We instantiate the integer references in  $s_{n-1}$  according to the model found **Fig. 8**. State  $Z'$  for  $\varphi$ , yielding a state  $s'_{n-1} \sqsubseteq s_{n-1}$ . So in our example (where  $s_n = s$  is  $N$  and  $s_{n-1}$  is  $Z$ ), we instantiate  $i_6$  and  $i_8$  in  $Z$  by 1 resp. 0, resulting in the state  $Z'$  in Fig. 8 (i.e., here  $s'_{n-1}$  is  $Z'$ ).

Afterwards, we traverse the path from  $s_{n-1}$  backwards to  $s_0$  and use the technique of witness generation from Sect. 3 to generate a witness  $v$  for  $s_0$  w.r.t.  $s'_{n-1}$

(i.e.,  $v \sqsubseteq s_0$  such that  $v \xrightarrow{\text{SyEv}}^+ v'$  for some  $v' \sqsubseteq s'_{n-1}$ ). In our example,<sup>12</sup> the

<sup>11</sup> Remember that we use a single static assignment technique. Thus, we do not have to perform renamings to avoid name clashes.

<sup>12</sup> During the witness generation, one again uses the model of  $\varphi$  for intermediate integer references. So when reversing the `iadd` evaluation between  $Y$  and  $Z$ , we choose 0 as value for the newly appearing reference  $i_7$ .

```
05|a:a3,i:0,j:1|ε
a3:String[] 1
```

**Fig. 8.** State  $Z'$

```
05|a:a3,i:0,j:1|ε
a3:String[] 1 {o6}
o6:String(count=0,...)
```

**Fig. 9.** State  $N'$

witness generation results in the state  $N'$  in Fig. 9. Note that the witness generation technique automatically “guessed” a suitable instantiation for the array (i.e., it was instantiated by a 1-element array containing just the empty string). Indeed,  $N' \sqsubseteq N$  and  $N' \xrightarrow{SyEv} v'$  for an instance  $v'$  of  $Z'$  (i.e., in our example  $s_0 = s$  is  $N$  and  $v$  is  $N'$ ). Here,  $v'$  is like  $Z'$ , but instead of “ $a_3:\text{String}[1]$ ”, we have “ $a_3:\text{String}[1]\{o_6\}$ ” and “ $o_6:\text{String}(\text{count}=0, \dots)$ ”. Thus,  $v' = N'$ .

3. *Check whether the guessed values for non-integer references do not change in the loop.* While our construction ensures that the interesting *integer* references remain unchanged when executing the loop, this is not ensured for the interesting non-integer references. Hence, in the third step, we now have to check whether  $v' \sqsubseteq_{\Pi} v$  holds, where  $\Pi$  are the positions of interesting references in  $s$ .

To this end, we adapt our algorithm `mergeStates(v, v')` such that it terminates with failure whenever we widen a value of  $v$  or add an annotation that did not exist in  $v$  at a position with a prefix from  $\Pi$ . Then the algorithm terminates successfully iff  $v' \sqsubseteq_{\Pi} v$ . In our example where  $v = v' = N$ , we clearly have  $v' \sqsubseteq_{\Pi} v$ . Hence by Thm. 7, any instance of  $v$  (i.e., of  $N'$ ) starts an infinite execution.

4. *Check whether the non-terminating loop can be reached from the initial state.* In the fourth step, we finally check whether  $N'$  can be reached from the initial state of the method. Hence, we again use the witness generation technique from Sect. 3 to create a witness state for  $A$  w.r.t.  $N'$ . This witness state has the stack frame “ $00 \mid \mathbf{a} : a_3 \mid \varepsilon$ ” where  $a_3$  is a 1-element array containing just the empty string. In other words, we automatically synthesized the counterexample to termination indicated in problem (b) of Sect. 2.

## 4.2 Non-Looping Non-Termination

```
static void nonLoop(
  int x, int y) {
  if (y >= 0) {
    while(x >= y) {
      int z = x - y;
      if (z > 0) {
        x--;
      } else {
        x = 2*x + 1;
        y++; }}}}

```

**Fig. 10.** `nonLoop(x,y)`

A loop can also be non-terminating if the values of interesting references are modified in its body. We now present a method to find such *non-looping* forms of non-termination. In contrast to the technique of Sect. 4.1, this method is restricted to loops that have no sub-loops and whose termination behavior only depends on integer arithmetic (i.e., the interesting references in all states of the loop may only refer to integers). Then we can construct a formula that represents the loop condition and the computation on each path through the loop. If we can prove that no variable assignment that satisfies the loop condition violates it in the next loop iteration, then we can conclude non-termination under the condition that the loop condition is satisfiable.

The method `nonLoop` in Fig. 11 does not terminate if  $x \geq y \geq 0$ . For example, if  $x = 2, y = 1$  at the beginning of the loop, then after one iteration we have  $x = 1, y = 1$ . In the next iterations, we obtain  $x = 3, y = 2$ ;  $x = 2, y = 2$ ; and  $x = 5, y = 3$ , etc. So this non-termination is non-looping and even *non-periodic* (since there is no fixed sequence of program positions that is repeated infinitely many times). Thus, non-termination cannot be proved by techniques like [14].

Consider the termination graph, which is shown in a simplified version in

Fig. 11. A node in a cycle with a predecessor outside of the cycle is called a *loop head node*. In Fig. 11,  $A$  is such a node. We consider all paths  $p_1, \dots, p_n$  from the loop head node back to itself (without traversing the loop head node in between), i.e.,  $p_1 = A, \dots, B, A$  and  $p_2 = A, \dots, C, A$ . Here,  $p_1$  corresponds to the case where  $x \geq y$  and  $z = x - y > 0$ , whereas  $p_2$  handles the case where  $x \geq y$  and  $z = x - y \leq 0$ . For each path  $p_j$ , we generate a *loop condition formula*  $\varphi_j$  (expressing the condition for entering this path) and a *loop body formula*  $\psi_j$  (expressing how the values of the interesting references are changed in this path).

Fig. 11. Graph for nonLoop

The formulas  $\varphi_j$  and  $\psi_j$  are generated as in Step 1 of Sect. 4.1, where we add relations from  $\mathcal{RelOp}$  to  $\varphi_j$  and constraints from  $\mathcal{ArithOp}$  to  $\psi_j$ . In our example,  $\varphi_1$  is  $i_1 \geq i_2 \wedge i_3 > 0$  and  $\varphi_2$  is  $i_1 \geq i_2 \wedge i_3 \leq 0$ . Moreover,  $\psi_1$  is  $i_3 = i_1 - i_2 \wedge i_4 = i_1 - 1$  and  $\psi_2$  is  $i_3 = i_1 - i_2 \wedge i_5 = 2 \cdot i_1 \wedge i_6 = i_5 + 1 \wedge i_7 = i_2 + 1$ . To connect these formulas, we use a labeling function  $\ell^k$  where for any formula  $\xi$ ,  $\ell^k(\xi)$  results from  $\xi$  by labeling all variables with  $k$ . We use the labels  $1, \dots, n$  for the paths through the loop and the label  $r$  for the resulting variables (in the second run, leaving the loop). We construct the formula

$$\rho(p_1, \dots, p_n) = \underbrace{\mu}_{\text{invariants}} \wedge \underbrace{\left( \bigvee_{j=1}^n (\ell^j(\varphi_j) \wedge \ell^j(\psi_j) \wedge \iota_j) \right)}_{\text{first run through the loop}} \wedge \underbrace{\left( \bigwedge_{j=1}^n (\neg \ell^r(\varphi_j) \wedge \ell^r(\psi_j)) \right)}_{\text{second run, leaving the loop}}$$

Here,  $\mu$  is a set of invariants that are known in the loop head node. So as we know “ $i_2: [\geq 0]$ ” in state  $A$ ,  $\mu$  is  $i_2 \geq 0$  for our example. The formula  $\iota_j$  connects the variables labeled with  $j$  to the unlabeled variables in  $\mu$  and to the variables labeled with  $r$  in the formulas for the second iteration. So for every integer reference  $i$  in the loop head node,  $\iota_j$  contains  $i = i^j$ . Moreover, if  $i$  is an integer reference at position  $\pi$  in the loop head node  $s$  and  $i'$  is at position  $\pi$  in the predecessor  $s'$  of  $s$  (where there is an instance edge from  $s'$  to  $s$ ), then  $\iota_j$  contains  $i'^j = i^r$ . For our example,  $\iota_1$  is  $i_1 = i_1^1 \wedge i_2 = i_2^1 \wedge i_4 = i_1^1 \wedge i_2^1 = i_2^r$ .

Intuitively, satisfiability of the first two parts of  $\rho(p_1, \dots, p_n)$  corresponds to one successful run through the loop. The third part encodes that none of the loop conditions holds in the next run. Here, we do not only consider the negated conditions  $\neg \ell^r(\varphi_j)$ , but we also need  $\ell^r(\psi_j)$ , as  $\varphi_j$  can contain variables computed in the loop body. For example in **nonLoop**,  $\ell^r(\varphi_1)$  contains  $i_3^r > 0$ . But to determine how  $i_3^r$  results from the “input arguments”  $i_1^r, i_2^r$ , one needs  $\ell^r(\psi_1)$  which contains  $i_3^r = i_1^r - i_2^r$ . If an SMT solver proves unsatisfiability of  $\rho(p_1, \dots, p_n)$ , we know that whenever a variable assignment satisfies a loop condition, then after one execution of the loop body, a loop condition is satisfied again (i.e., the loop runs forever). Note that we generalized the notion of “loop conditions”, as we discover the conditions by symbolic evaluation of the loop. Consequently, we can also handle loop control constructs like **break** or **continue**.

So unsatisfiability of  $\rho(p_1, \dots, p_n)$  implies that the loop is non-terminating, provided that the loop condition can be satisfied at all. To check this, we use an SMT solver to find a model for  $\sigma(p_1, \dots, p_n) = \mu \wedge \left( \bigvee_{j=1}^n (\ell^j(\varphi_j) \wedge \ell^j(\psi_j) \wedge \iota_j) \right)$ .

**Theorem 8 (Non-Looping Non-Termination).** *Let  $s$  be a loop head node in a termination graph where  $I(s)$  only point to integer values and let  $p_1, \dots, p_n$  be all paths from  $s$  back to  $s$ . Let  $\rho(p_1, \dots, p_n)$  be unsatisfiable and let  $\sigma(p_1, \dots, p_n)$  be satisfiable by some model  $M$  (i.e.,  $M$  is an assignment of integer references to concrete integers). Let  $c \sqsubseteq s$  be a concrete state where every integer reference in  $c$  has been assigned the value given in  $M$ . Then  $c$  starts an infinite JBC evaluation.*

From the model  $M$  of  $\sigma(p_1, \dots, p_n)$ , we obtain an instance  $v$  of the loop head node where we replace unknown integers by the values in  $M$ . Then the technique from Sect. 3 can generate a witness for the initial state of the method w.r.t.  $v$ . For our example,  $i_1 = i_1^1 = i_3^1 = 1, i_2 = i_2^1 = i_4^1 = i_1^r = 0$  satisfies  $\sigma(p_1, \dots, p_n)$ . From this, we obtain a witness for the initial state with  $\mathbf{x} = 1$  and  $\mathbf{y} = 0$ , i.e., we automatically generate a non-terminating counterexample.

## 5 Evaluation and Conclusion

Based on termination graphs for Java Bytecode, we presented a technique to generate witnesses w.r.t. arbitrary error states. We then showed how to use this technique to prove the reachability of `NullPointerException`s or of non-terminating loops, which we detect by a novel SMT-based technique.

We implemented our new approach in the termination tool AProVE [12], using the SMT solver Z3 [10] and evaluated it on a collection of 325 examples. They consist of all 268 JBC programs from the *Termination Problem Data Base* that is used in the annual *International Termination Competition*,<sup>13</sup> all 55 examples from [24] used to evaluate the Invel tool, and the two examples from this paper. For our evaluation, we compared the old version of AProVE (without support for non-termination), the new version AProVE-No containing the results of the present paper, and Julia [20]. We were not able to obtain a running version of Invel, and thus we only compared to the results of Invel reported in [24].

We used a time-out of 60 seconds for each example. “**Y**es” and “**N**o” indicate how often termination (resp. non-termination) could be proved, “**F**ail” states how often the tool failed in less than 1 minute, “**T**” indicates how many examples

	Invel Ex.					Other Ex.				
	Y	N	F	T	R	Y	N	F	T	R
AProVE-No	1	51	0	3	5	204	30	12	24	11
AProVE	1	0	5	49	54	204	0	27	39	15
Julia	1	0	54	0	2	166	22	82	0	4
Invel	0	42	13	0	?					

led to a **T**ime-out, and “**R**” gives the average **R**untime in seconds for each example. The experiments clearly show the power of our contributions, since AProVE-No is the most powerful tool for automated non-termination proofs of Java resp. JBC programs. Moreover, the comparison between AProVE-No and AProVE indicates that the runtime for termination proofs did not increase due to the added non-termination techniques. To experiment with our implementation via a web interface and for details on the experiments, we refer to [1].

## Appendix A. Proofs

To give the proof for Thm. 2, we first recapitulate the formal definition of “instance” from [4, Def. 3], where we extended it in order to handle arrays.

**Definition 9 (Instance).** Let  $s' = (\langle fr'_0, \dots, fr'_n \rangle, e', h', a')$  and  $s = (\langle fr_0, \dots, fr_n \rangle, e, h, a)$ , where  $fr'_i = (pp'_i, lv'_i, os'_i)$  and  $fr_i = (pp_i, lv_i, os_i)$ . We call  $s'$  an instance of  $s$  (denoted  $s' \sqsubseteq s$ ) iff  $pp_i = pp'_i$  for all  $i$  and for all  $\pi, \pi' \in \text{SPOS}(s')$ :

- (a) if  $h'(s'|\pi) \in \text{INTEGERS}$  and  $\pi \in \text{SPOS}(s)$ , then  $h'(s'|\pi) \subseteq h(s|\pi) \in \text{INTEGERS}$ .
- (b) if  $h'(s'|\pi) = \text{null}$  and  $\pi \in \text{SPOS}(s)$ , then  $h(s|\pi) \in \{\text{null}\} \cup \text{UNKNOWN}$ .
- (c) if  $h'(s'|\pi) = (t', ?) \in \text{UNKNOWN}$  and  $\pi \in \text{SPOS}(s)$ , then  $h(s|\pi) = (t, ?) \in \text{UNKNOWN}$  and  $t'$  is a subtype of  $t$ .
- (d) if  $h'(s'|\pi) = (t', i') \in \text{ARRAYS}$  and  $\pi \in \text{SPOS}(s)$ , then  $h(s|\pi) = (t, i) \in \text{ARRAYS}$  or  $h(s|\pi) = (t, ?) \in \text{UNKNOWN}$  and  $t'$  is a subtype of  $t$
- (e) if  $h'(s'|\pi) = (t', i', d') \in \text{ARRAYS}$  and  $\pi \in \text{SPOS}(s)$ , then  $h(s|\pi) = (t, i, d) \in \text{ARRAYS}$  or  $h(s|\pi) = (t, i) \in \text{ARRAYS}$  or  $h(s|\pi) = (t, ?) \in \text{UNKNOWN}$  and  $t'$  is a subtype of  $t$
- (f) if  $h'(s'|\pi) = (cl', f') \in \text{INSTANCES}$  and  $\pi \in \text{SPOS}(s)$ , then  $h(s|\pi) = (cl, ?)$  or  $h(s|\pi) = (cl', f) \in \text{INSTANCES}$ , where  $cl'$  must be a subtype of  $cl$ .
- (g) if  $s'|\pi \neq s'|\pi'$  and  $\pi, \pi' \in \text{SPOS}(s)$ , then  $s|\pi \neq s|\pi'$ .
- (h) if  $s'|\pi = s'|\pi'$  and  $\pi, \pi' \in \text{SPOS}(s)$  where  $h'(s'|\pi) \notin \text{INTEGERS} \cup \{\text{null}\}$ , then  $s|\pi = s|\pi'$  or  $s|\pi = ? s|\pi'$ .
- (i) if  $s'|\pi = ? s'|\pi'$  and  $\pi, \pi' \in \text{SPOS}(s)$ , then  $s|\pi = ? s|\pi'$ .
- (j) if  $(s'|\pi = s'|\pi'$  or  $s'|\pi = ? s'|\pi'$  where  $h'(s'|\pi) \notin \text{INTEGERS} \cup \{\text{null}\}$ ) and  $\{\pi, \pi'\} \not\subseteq \text{SPOS}(s)$  with  $\pi \neq \pi'$ , then  $s|\pi \not\sqsubseteq s|\pi'$ .
- (k) if  $s'|\pi \not\sqsubseteq s'|\pi'$ , then  $s|\pi \not\sqsubseteq s|\pi'$ .
- (l) if  $s'|\pi!$ , then  $s|\pi!$ .
- (m) if there exist  $\rho, \rho' \in (\text{FIELDIDS} \cup \text{ARRAYIDX})^*$  without common non-empty prefix where  $\rho \neq \rho'$ ,  $s'|\pi_\rho = s'|\pi_{\rho'}$ ,  $h'(s'|\pi_\rho) \notin \text{INTEGERS} \cup \{\text{null}\}$ , and  $(\{\pi_\rho, \pi_{\rho'}\} \not\subseteq \text{SPOS}(s)$  or  $s|\pi_\rho = ? s|\pi_{\rho'}$ ), then  $s|\pi!$ .

To prove the soundness of the algorithm `mergeStates`, we repeat its definition with added line numbers in Fig. 12.

**Theorem 2.** Let  $s, s' \in \text{STATES}$  and  $\hat{s} = \text{mergeStates}(s, s')$ . Then  $s \sqsubseteq \hat{s} \sqsupseteq s'$ .

*Proof.* We only show  $s \sqsubseteq \hat{s}$ , as  $s' \sqsubseteq \hat{s}$  is completely analogous. Let  $h$  be the heap of  $s$  and  $\hat{h}$  be the heap of  $\hat{s}$ . We assume that the algorithm never adds the annotation  $\hat{s}|\pi = ? \hat{s}|\pi'$  for  $\hat{h}(\hat{s}|\pi), \hat{h}(\hat{s}|\pi') \notin \text{UNKNOWN}$ . If that happens in line 10 of the algorithm, we replace one of the two values  $\hat{h}(\hat{s}|\pi)$  or  $\hat{h}(\hat{s}|\pi')$  by a value from `UNKNOWN` to be compatible with our requirement that in any annotation  $o_1 = ? o_2$ , at least one of the references points to a value from `UNKNOWN`. Then we restart the annotation computation in line 6.

We prove  $s \sqsubseteq \hat{s}$  by checking each of the conditions from Def. 9. Let  $\pi, \pi' \in \text{SPOS}(s)$ :

```

Algorithm mergeStates( $s, s'$ ):
01  $\hat{s} = \text{new State}(s)$ 
02 for  $\pi \in \text{SPOS}(s) \cap \text{SPOS}(s')$ :
03    $\text{ref} = \text{mergeRef}(s|_{\pi}, s'|_{\pi})$ 
04    $\hat{h}(\text{ref}) = \text{mergeVal}(h(s|_{\pi}), h'(s'|_{\pi}))$ 
05    $\hat{s}|_{\pi} = \text{ref}$ 
06 for  $\pi \neq \pi' \in \text{SPOS}(s)$ :
07   if  $(s|_{\pi} = s|_{\pi'} \vee s|_{\pi} =^? s|_{\pi'})$ 
08      $\wedge h(s|_{\pi}) \notin \text{INTEGERS} \cup \{\text{null}\}$ :
09     if  $\pi, \pi' \in \text{SPOS}(\hat{s})$ :
10       if  $\hat{s}|_{\pi} \neq \hat{s}|_{\pi'} : \text{Set } \hat{s}|_{\pi} =^? \hat{s}|_{\pi'}$ 
11     else:
12        $\text{Set } \hat{s}|_{\bar{\pi}} \searrow \hat{s}|_{\bar{\pi}'}$ 
13   if  $s|_{\pi} \searrow s|_{\pi'} : \text{Set } \hat{s}|_{\bar{\pi}} \searrow \hat{s}|_{\bar{\pi}'}$ 
14 for  $\pi \in \text{SPOS}(s)$ :
15   if  $s|_{\pi}!$ :  $\text{Set } \hat{s}|_{\bar{\pi}}!$ 
16   if  $\exists \rho \neq \rho' : \pi\rho, \pi\rho' \in \text{SPOS}(s) \wedge s|_{\pi\rho} = s|_{\pi\rho'}$ 
17      $\wedge \rho, \rho'$  have no common prefix  $\neq \varepsilon$ 
18      $\wedge h(s|_{\pi\rho}) \notin \text{INTEGERS} \cup \{\text{null}\}$ :
19     if  $\pi\rho, \pi\rho' \in \text{SPOS}(\hat{s}) \wedge \hat{s}|_{\pi\rho} \neq \hat{s}|_{\pi\rho'}$ :

**Fig. 12.** Merging Algorithm

- (a)-(f): These conditions hold due to the (correct) merging of values by `mergeVal` in line 4.
- (g): If  $s|_{\pi} \neq s|_{\pi'}$  and  $\pi, \pi' \in \text{SPOS}(\hat{s})$ , then by construction  $\pi, \pi' \in \text{SPOS}(s')$  and thus  $\hat{s}|_{\pi} = \text{mergeRef}(s|_{\pi}, s'|_{\pi})$  and  $\hat{s}|_{\pi'} = \text{mergeRef}(s|_{\pi'}, s'|_{\pi'})$ . Since `mergeRef` is injective, we have  $\hat{s}|_{\pi} \neq \hat{s}|_{\pi'}$ .
- (h): If  $s|_{\pi} = s|_{\pi'}$ ,  $h(s|_{\pi}) \notin \text{INTEGERS} \cup \{\text{null}\}$ , and  $\pi, \pi' \in \text{SPOS}(\hat{s})$ , then  $\hat{s}|_{\pi} = \hat{s}|_{\pi'}$  or by line 10,  $\hat{s}|_{\pi} =^? \hat{s}|_{\pi'}$ .
- (i): Analogous to (h).
- (j): If  $\pi \neq \pi'$ ,  $s|_{\pi} = s|_{\pi'}$  or  $s|_{\pi} =^? s|_{\pi'}$ ,  $h(s|_{\pi}) \notin \text{INTEGERS} \cup \{\text{null}\}$ , and  $\{\pi, \pi'\} \not\subseteq \text{SPOS}(\hat{s})$ , then  $\hat{s}|_{\bar{\pi}} \searrow \hat{s}|_{\bar{\pi}'}$  by line 12.
- (k), (l): Similar to (j) (by line 13 resp. line 15).
- (m): If  $\rho, \rho'$  have no common non-empty prefix,  $\rho \neq \rho'$ ,  $s|_{\pi\rho} = s|_{\pi\rho'}$ , and  $h(s|_{\pi\rho}) \notin \text{INTEGERS} \cup \{\text{null}\}$ , then  $\pi\rho, \pi\rho' \in \text{SPOS}(\hat{s})$  and  $\hat{s}|_{\pi\rho} = \hat{s}|_{\pi\rho'}$ , or  $\pi\rho, \pi\rho' \in \text{SPOS}(\hat{s})$  and  $\hat{s}|_{\pi\rho} =^? \hat{s}|_{\pi\rho'}$  and by line 20,  $\hat{s}|_{\bar{\pi}}!$ , or  $\{\pi\rho, \pi\rho'\} \not\subseteq \text{SPOS}(\hat{s})$  and by line 21, we have  $\hat{s}|_{\bar{\pi}}!$ .  $\square$

**Theorem 5 (Generating Witnesses).** *Let  $(s_1, l, s_2)$  be an edge in the termination graph and let  $s'_2$  be a witness state for  $s_2$  w.r.t.  $w$ . Let  $s'_1 \in \text{STATES}$  with:*

- if  $l = \text{EVAL}_C$ , then  $s'_1$  is obtained from  $s'_2$  by applying the symbolic evaluation used between  $s_1$  and  $s_2$  backwards. In  $s'_1$ , we instantiate freshly appearing variables such that  $s'_1 \sqsubseteq s_1$  and  $s'_1 \xrightarrow{\text{SyEv}} s'_2$  holds.
- if  $l = \text{REFINE}_R$ , then  $s'_1 \sqsubseteq s'_2$ .
- if  $l = \text{INS}$ , then  $s'_1 = s_1 \cap s'_2$  (for the definition of  $\cap$ , see [6, Def. 2]).

Then  $s'_1$  is a witness state for  $s_1$  w.r.t.  $w$ .

*Proof.* For evaluation edges, we have  $s'_1 \sqsubseteq s_1$  and  $s'_1 \xrightarrow{\text{SyEv}} s'_2 \xrightarrow{\text{SyEv}*} w'$  for an instance  $w' \sqsubseteq w$ , since  $s'_2$  is a witness state w.r.t.  $w$ .

For refinement edges, we have  $s_2 \sqsubseteq s_1$ . As  $s'_2$  is a witness for  $s_2$  (and thus  $s'_2 \sqsubseteq s_2$ ), we obtain  $s'_1 \sqsubseteq s'_2 \sqsubseteq s_2 \sqsubseteq s_1$ . Moreover, since  $s'_2 \xrightarrow{\text{SyEv}*} w'$  for an instance  $w' \sqsubseteq w$ ,  $s'_1 \sqsubseteq s'_2$  implies that  $s'_1 \xrightarrow{\text{SyEv}*} w''$  for an instance  $w'' \sqsubseteq w' \sqsubseteq w$ .

For instance edges,  $s'_1 = s_1 \cap s'_2$  implies  $s'_1 \sqsubseteq s_1$  and  $s'_1 \sqsubseteq s'_2$ . Hence, we obtain  $s'_1 \xrightarrow{\text{SyEv}*} w''$  for an instance  $w'' \sqsubseteq w$  as for refinement edges.  $\square$

**Theorem 7 (Looping Non-Termination).** *Let  $s$  occur in a cycle of the termination graph. Let  $\Pi = \{\pi \in \text{SPOS}(s) \mid s|_\pi \in I(s)\}$  be the positions of interesting references in  $s$ . If there is a  $v \sqsubseteq s$  where  $v \xrightarrow{\text{SyEv}^+} v'$  for some  $v' \sqsubseteq_\Pi v$ , then any concrete state that is an instance of  $v$  starts an infinite JBC evaluation.*

*Proof.* Let  $s = s_0, \dots, s_n = s$  be the cyclic path from  $s$  to  $s$  in the termination graph. We assume that there is a concrete state  $c \sqsubseteq v$  that starts no infinite computation. As  $v \xrightarrow{\text{SyEv}^+} v'$ , there is a corresponding concrete JBC evaluation  $c \xrightarrow{\text{SyEv}^+} c'$  with  $c' \sqsubseteq v'$ . As  $v' \sqsubseteq_\Pi v \sqsubseteq s$ , this corresponds to one run through the loop.

By assumption,  $c$  and hence,  $c'$  start no infinite computation. Thus when continuing the evaluation of  $c'$ , one stays within the loop for some more time, but then one leaves the loop. Let  $e$  be the last state in the evaluation of  $c'$  that is still within the loop and let  $e'$  be the first state in this evaluation which is outside the loop. So we have  $c' \xrightarrow{\text{SyEv}*} e \xrightarrow{\text{SyEv}} e'$  and there is a state  $s_i$  from the loop with  $e \sqsubseteq s_i$  but  $e' \not\sqsubseteq s_{i+1}$  (i.e.  $e \xrightarrow{\text{SyEv}} e'$  is the evaluation step where the loop is left).

In the termination graph, the state  $s_i$  has several successors (at least one in the loop and one outside of it). By soundness of the graph construction,  $e'$  is an instance of one of the successors of  $s_i$ .

By the definition of termination graphs, the only states with more than one successor are states with outgoing refinement edges. Let  $R$  be the set of references that these edges are marked with. Then the references from  $R$  are interesting in  $s_i$  and by the definition of interesting references, the corresponding references are also interesting in  $s$ . This means that  $\Pi$  contains the positions of those references whose values determine whether one leaves the loop in an instance of  $s_i$ .

Let  $v_i \sqsubseteq s_i$  be the state in the evaluation  $v \xrightarrow{SyEv^+} v'$  that corresponds to the state  $s_i$  (i.e.,  $v \xrightarrow{SyEv^*} v_i \xrightarrow{SyEv^*} v'$ ). Since  $c' \sqsubseteq v' \sqsubseteq_{\Pi} v$  and since the evaluation steps that evaluated  $c'$  to  $e$  were also used to evaluate  $v$  to  $v_i$ , we also obtain  $e \sqsubseteq_{\Pi} v_i$ . Note that when evaluating  $v_i$  further, we stay in the loop. But as  $\Pi$  contains the positions of those references whose values determine whether one leaves the loop, one obtains a corresponding evaluation in  $e$ , i.e., one cannot leave the loop when evaluating  $e$ . In other words, the successor state  $e'$  cannot be outside the loop, which is a contradiction.  $\square$

**Theorem 8 (Non-Looping Non-Termination).** *Let  $s$  be a loop head node in a termination graph where  $I(s)$  only point to integer values and let  $p_1, \dots, p_n$  be all paths from  $s$  back to  $s$ . Let  $\rho(p_1, \dots, p_n)$  be unsatisfiable and let  $\sigma(p_1, \dots, p_n)$  be satisfiable by some model  $M$  (i.e.,  $M$  is an assignment of integer references to concrete integers). Let  $c \sqsubseteq s$  be a concrete state where every integer reference in  $c$  has been assigned the value given in  $M$ . Then  $c$  starts an infinite JBC evaluation.*

*Proof.* Assume that  $c$  does not start an infinite evaluation, i.e., its evaluation is finite. We now consider the sequence  $c = c_0 \xrightarrow{SyEv^+} c_1 \xrightarrow{SyEv^+} \dots \xrightarrow{SyEv^+} c_{m-1} \xrightarrow{SyEv^+} c_m$ , which is part of this evaluation. Here, all  $c_i$  are instances of the loop head node  $s$  and all states in the computations between  $c_i$  and  $c_{i+1}$  are no instances of  $s$ . Moreover, no state reached after  $c_m$  in the evaluation is an instance of  $s$ . We know that  $m$  is at least 1, as  $M$  is a satisfying assignment for the disjunction of loop conditions  $\sigma(p_1, \dots, p_n)$  and thus, the loop is traversed at least once.

From the values of the integer variables in  $c_{m-1}$ , we can construct another assignment  $M'$  satisfying  $\sigma(p_1, \dots, p_n)$ , as by construction, the loop is traversed once more (leading to  $c_m$ ). But as the loop is left after reaching  $c_m$ , none of the loop conditions  $\ell^r(\varphi_j)$  holds for these values. Moreover,  $M'$  can also be extended to satisfy all  $\ell^r(\psi_j)$ , which are conjunctions of equations of the form  $i = i' \bowtie i''$ , where  $i$  is always a fresh variable. Then  $M'$  is also satisfying assignment for  $\rho(p_1, \dots, p_n)$ , which contradicts its unsatisfiability.  $\square$
